Introduction
Since the adoption of the Growth Model Pilot Program (GMPP) nearly a decade ago, estimation of growth models for evaluation and accountability purposes has been gaining traction across the country.\(^1\) Advances in statistical methodology, coupled with modern computing power, allow for rich and flexible modeling of many factors potentially underlying students’ performance on standardized tests. Among some of the more popular growth models currently used by districts and states to estimate growth are Value-Added Models (VAMs) and Student Growth Percentiles (SGPs). Both models use sophisticated statistical techniques and large samples of test score data to estimate individual students’ growth. The output of VAMs and SGPs are then used for a variety of evaluative purposes. Despite the increasing popularity of these models, the literature on educational measurement and evaluation continues to suggest using caution when “high-stakes” accountability decisions are based on these measures of student growth. The issue is, regardless of the growth model, aggregate test-score-based models of student growth require large and longitudinally connected samples of student data. When sample sizes are small it becomes impossible to reliably estimate and disentangle district, school, and teacher effects from student growth data.

Small Samples
Small samples are of particular concern in the context of special student subgroups like English Learners (ELs). High student mobility, frequently interrupted education, and complex teacher–student linkage are among some of the EL-specific factors exacerbating the problem of insufficient sample sizes. Figure 1 presents the distribution of WIDA’s 27,016 schools by size (classified as “Micro,” “Small,” “Medium,” and “Large”) as determined by the number of ELs with connected ACCESS for ELLs (ACCESS) Composite Scale Scores across the 2013–2014 ACCESS test administrations.

\(^1\) The GMPP report is available online at: http://www2.ed.gov/rschstat/eval/disadv/growth-model-pilot/gmpp-final.pdf
Figure 1 shows that about half of WIDA’s schools had fewer than 10 enrolled ELs with connected ACCESS for ELLs test growth scores. An additional third of the schools that we label as “Small” had fewer than 50 enrolled ELs, and many of these ELs are further nested across multiple teachers. Regardless of the selected growth model, for a large majority of WIDA’s schools (about 8 out of 10), the statistical estimation of both teacher- and school-effects would be based on small samples of ELs, resulting in high imprecision and cross-year instability in the growth estimates.

**Attribution**

In addition to small sample sizes, the attribution of growth effects becomes challenging with respect to assigning EL teachers’ contributions to students’ growth. Difficulties arise in defining how a single teacher affects student growth, given the complex and often varying assignment schedule of teachers to ELs. The inherent diversity within the EL population that places many students in unique paths to proficiency further complicates model estimation. ELs vary in their starting English language proficiency and age, prior education, home language proficiency, and types of the instructional programs they are enrolled in. Even when it is technically possible to match a group of EL students with a single EL teacher, it is overly simplistic to ignore the effect of all these potentially confounding factors, which in many cases are outside of the schools’ or teachers’ control. Further, is it plausible to assume that only one teacher contributes to students’ academic English language development, dismissing influence of other educators or student involvement in other school or academically related activities? Attributing EL students’ growth in language proficiency development to an individual teacher is fraught with complexities, which can only add to the imprecision and instability of growth effects.

**Conclusion**

Issues with small samples and teacher-student attribution introduce a multitude of problems, casting doubt on the accuracy and stability of growth estimates based on aggregated EL student test scores. WIDA recommends that educational agencies NOT make high-stakes decisions using growth models based on ACCESS test scores unless the issue of sample size and attribution has been overcome.
